In this study, the Y was systematically surveyed for further long-range polymorphisms, by the hybridization of 33 probes to Sfi digests of DNA from males of different ethnic origins and from the two groups. Five novel polymorphisms were identified, all showing variability consistent with a changing number of tandem repeats within an array.

DNA polymorphisms can result in important functional changes in drug target molecules. One example is the common R389G (substitution of glycine for arginine at position 389) variant in ADR1 encoding the ? 1-adrenergic receptor. The R389 variant demonstrated a two- to four-fold greater increase in myocyte contractility during exposure to ?-agonists and predicted a beneficial response of patients with heart failure receiving bucindolol; in fact, clinical response in G389 carriers was no ...

A DNA polymorphism is a DNA sequence variation that is not associated with any observable phenotypic variation, and can exist anywhere in the genome, not necessarily in a gene. Polymorphism means one of two or more alternative forms (alleles) of a chromosomal region that either has a different nucleotide sequence, or it has variable numbers of tandemly repeated nucleotides.

~~DNA Polymorphisms: Meaning and Classes | Genetics~~

In biology, polymorphism is the occurrence of two or more clearly different morphs or forms, also referred to as alternative phenotypes, in the population of a species. To be classified as such, morphs must occupy the same habitat at the same time and belong to a panmictic population (one with random mating).

Restriction fragment length polymorphisms (RFLPs) have several advantages over conventional genetic markers and as a result have received increased attention from plant breeders and geneticists. The objective of this study was to construct a tall fescue (Festuca arundinacea Schreb.) genomic library and to survey RFLPs in tall fescue and its relatives.
