Exponential smoothing is generally used for the analysis of time-series data. Exponential Smoothing Formula. The simplest form of an exponential smoothing formula is given by: $s_t = \alpha x_t + (1 - \alpha)s_{t-1} = s_{t-1} + \alpha(x_t - s_{t-1})$ Here, s_t = smoothed statistic, it is the simple weighted average of current observation x_t . s_{t-1} = previous smoothed statistic

Exponential Smoothing S U Exponential smoothing is a rule of thumb technique for smoothing time series data using the exponential window function. Whereas in the simple moving average the past observations are weighted equally, exponential functions are used to assign exponentially decreasing weights over time.

Exponential smoothing is a rule of thumb technique for smoothing time series data using the exponential window function. Whereas in the simple moving average the past observations are weighted equally, exponential functions are used to assign exponentially decreasing weights over time. It is an easily learned and easily applied procedure for making some determination based on prior assumptions by the user, such as seasonality.

Exponential forecasting is another smoothing method and has been around since the 1950s. Where naive forecasting places 100% weight on the most recent observation and moving averages place equal weight on k values, exponential smoothing allows for weighted averages where greater weight can be placed on recent observations and lesser weight on older observations. Exponential smoothing methods are intuitive, computationally efficient, and generally applicable to a wide range of time series.

The Exponential Smoothing is a technique for smoothing data of time series using an exponential window function. It is a rule of the thumb method. Unlike simple moving average, over time the exponential functions assign exponentially decreasing weights. Here the greater weights are placed on the recent values or observations while the lesser weights are placed on the older values or observations.
