~~Chapter 15 Transformer Design~~

The turns ratio, a , of a transformer is the ratio of the primary turns, N_1 , to the secondary turns, N_2 , or the ratio of the primary voltage, V_1 , to the secondary voltage, V_2 ; $a = N_1 / N_2 = V_1 / V_2$. Substitution of the values indicated in Fig. 4.1 for the turns ratio yields $a = 1000/500 = 2$. Secondary voltage $V_2 = V_1 / a = 120/2 = 60V$.

switchmode power supply transformer design. high current density power has been mitigated for the transformer designer because silicone devices such as IGBT's have current and frequency limits below what transformers can accommodate today. Thus, in an ideal transformer the Power Ratio is equal to one (unity) as the voltage, V multiplied by the current, I will remain constant. That is the electric power at one voltage/current level on the primary is “transformed” into electric power, at the same frequency, to the same voltage/current level on the secondary side. Although the transformer can step-up (or step-down) voltage, it ...
